Software-defined networking (SDN) is an architecture designed to make a network more flexible and easier to manage. SDN centralizes management by abstracting the control plane from the data forwarding function in the discrete networking devices.

### **What is Software-Defined Networking (SDN)? | VMware Glossary**

Software-defined networking (SDN) technology is an approach to network management that enables dynamic, programmatically efficient network configuration in order to improve network performance and monitoring, making it more like cloud computing than traditional network management. SDN is meant to address the fact that the static architecture of traditional networks is decentralized and complex while current networks require more flexibility and easy troubleshooting.

## **Software Defined Networking (SDN) explained for beginners**

How does software-defined networking (SDN) work? Here are the SDN basics: In SDN (like anything virtualized), the software is decoupled from the hardware. SDN moves the control plane that determines where to send traffic to software, and leaves the data plane that actually forwards the traffic in the hardware. This allows network administrators who use software-defined networking to program and control the entire network via a single pane of glass instead of on a device by device basis.

## **Bing: How Software Defined Networking Sdn**

What SDN does is view cloud-based services as just more network devices. So when you program how an application should be handled, that control will follow the program out to the cloud, or back to your local network, or wherever your devices exist. The other major reason is user programmability.
